Synthesis of 2-arylated thiadiazolopyrimidones by Suzuki–Miyaura cross-coupling: a new class of nucleotide pyrophosphatase (NPPs) inhibitors†

Behzad Jafari,⁎a Nazym Yelibayeva,a,b Meirambek Ospanov,a,b Syeda Abida Ejaz,c Saira Afzal,c Shafi Ullah Khan,c Zharylkasyn A. Abilov,b Mirgul Z. Turmukanova,b Sergey N. Kalugin,b Sayfedin Safarov,d Joanna Lecka,⁎e Jean Sévigny,⁎e Qamar Rahman,⁎a,g Peter Ehlers,⁎a,h Jamshed Iqbalf and Peter Langer⁎a,h

Over expression of nucleotide pyrophosphatase (NPPs) activity is associated with chondrocalcinosis, osteoarthritis, type 2 diabetes, neurodegenerative diseases, allergies and cancer metastasis. The potential of NPPs inhibitors as therapeutic agents, and the scarceness of their structure–activity relationship, encouraged us to develop new NPP inhibitors. Specifically, 2-bromo-7-methyl-5-oxo-5,1,3,4-thiadiazolopyrimidine and its corresponding 6-fluoro derivatives were synthesized via a Suzuki–Miyaura reaction. The cross-coupling reaction with different arylboronic acids gave desired coupling products in good to excellent yields and showed wide functional group tolerance. Furthermore, all compounds were investigated for their potential to inhibit two families of ecto-nucleotidases, i.e. nucleoside triphosphate diphosphohydrolases (NTPDase) and NPPs. Interestingly, our compounds were identified as selective inhibitors of NPPs. Among derivatives 5a–5i, compound 5i (IC50 ± SEM = 0.39 ± 0.01 μM) was found to be the most potent inhibitor of h-NPP1 and compound 5h (IC50 ± SEM = 1.02 ± 0.05 μM) was found to be the most potent inhibitor of h-NPP3. Similarly, for fluorinated thiadiazolopyrimidines, derivative 6e (IC50 ± SEM = 0.31 ± 0.01 μM) exhibited the best inhibition of NPP1 and it was found that this compound exhibited ≈28 fold improvement in inhibitory potential as compared with the reference control i.e. Suramin (IC50 ± SEM = 8.67 ± 1.3 μM). Moreover, homology modelling and molecular docking studies of both inhibitors were carried out to suggest the putative binding mode of inhibitors with the respective enzyme i.e. h-NPP1 and h-NPP3.

Introduction

Extracellular nucleotides and nucleosides are an important class of signaling molecules that are present in both the peripheral nervous system (PNS) and the central nervous system (CNS). Generally, nucleotides are released from the cells or by selective transport through the plasma membrane. But nucleotides can also be generated extracellularly by adenylate kinases and nucleoside diphosphokinases. Extracellular nucleotides exert their effects through two major receptor subfamilies P2X and P2Y. P2X receptors are ligand gated ion channels which consist of a family of seven receptors and mainly bind ATP. They are responsible for a large variety of responses including fast transmission at central synapses, macrophage activation, contraction of smooth muscle cells, platelet aggregation and apoptosis. Moreover these receptors also play a role in neurodegeneration, inflammation and cancer. On the other hand, P2Y receptors are a group of eight G-protein coupled receptors, which mainly bind both purine and pyrimidine nucleotides and are associated with cell cytotoxicity, differentiation, migration and cell proliferation mechanisms. Considering their significance in intracellular signaling, the extracellular level of nucleotides is tightly maintained by a variety of cell surface located enzymes named ecto-nucleotidases. In this regard, nucleoside triphosphate...
diphosphohydrolases (NTPDase) and nucleotide pyrophosphatase (NPPs) are of particular interest which regulate the nucleotide signaling by controlling the rate, timing and amount of nucleotide degradation. NTPDases represent a large family of ectonucleotidases which include eight members designated as NTPDase1–8. They dephosphorylate a variety of nucleoside triphosphates (e.g. ATP and UTP) and diphosphates (e.g., ADP and UDP) with different abilities and exclusively in the presence of divalent cations (Ca²⁺ or Mg²⁺). Each NTPDase member possesses different enzymatic properties and a separate cellular expression. They are responsible for the regulation of a multiplicity of biological processes, such as neurotransmission, cardiac function, liver glycogen metabolism and inflammation. Four members of this family, namely NTPDase1, NTPDase2, NTPDase3 and NTPDase8, are located at the surface of the plasma membrane and are responsible for controlling nucleotide signalling by activating P2 receptors. NTPDase1 hydrolyzes ATP and ADP equally. In contrast, NTPDase2 is a preferential triphosphonucleosidase, whereas NTPDase3 and NTPDase8 are functional intermediates between NTPDase1 and NTPDase2.

Another member of the same family, nucleotide pyrophosphatases (NPPs), are also involved in the hydrolysis of nucleotides. This family consists of seven closely related members that are numbered according to their order of discovery. They are widely distributed in tissues and exist either as transmembrane proteins or as secreted proteins in the extracellular space. To date, only three members, i.e. NPP1, NPP2 and NPP3, have been studied in detail. These members possess a wide range of substrate specificities and are responsible for hydrolyzing the pyrophosphate and phosphodiester bonds in a variety of compounds. For instance, NPP1 and NPP3 catalyze the hydrolysis of nucleoside tri/di phosphate, oligonucleotides, diadenosine polyphosphate, flavin adenine dinucleotides, nicotinamide adenine dinucleotide (NAD⁺), and uracil diphosphate (UDP) sugars. As these enzymes play an important role in maintaining a balanced level of nucleotides, they are of critical importance in nucleotide recycling, stimulation of cell motility, regulation of extracellular pyrophosphate levels and modulation of purinergic receptor signaling. In addition, they are also proposed to be involved in the regulation of insulin receptors and activity of ectokinases.

The presence of NPP1 has been described in various tissues, where its over expression can lead to many disorders, such as chondrocalcinosis or hypophosphatasia. Likewise, various other diseases, such as angiogenesis, type 2 diabetes, neurodegenerative disorders, bone mineralization dysfunction, cell motility and migration and tumor cell invasion have been associated with abnormal expression of NPPs. Numerous studies have established the importance of NPPs as potential...
targets for the treatment of various diseases including hypophosphatasia, chondrocalcinosis, and insulin resistance. Similarly, inhibitors of NPP3 may also find useful application in the treatment of neurodegenerative diseases and allergies as well as in the prevention of cancer metastasis.\textsuperscript{28} To date, many inhibitors of NPPs have been identified, but they often exhibit a non-selective behaviour on other ectonucleotidases. Therefore, there is a need to explore potent and selective inhibitors of NPPs that would be helpful in treating various relevant pathological conditions.

We have chosen thia diazolopyrimidinones as scaffold for our studies as this type of heterocyclic core structure represents an important scaffold in pharmaceutical research and shows a huge variety of biological activities which include activity against cancer,\textsuperscript{21} platelet aggregation,\textsuperscript{22} xanthine oxidase activity for the treatment of gout\textsuperscript{23} as well as activity for the medication of diseases related to central nervous system.\textsuperscript{24} Furthermore, related compounds are reported as antimicrobial, antibacterial, anti-allergic activity or anti-inflammatory agents.\textsuperscript{25} From the synthetic viewpoint we felt that the use of transition metal catalysed coupling reactions would greatly improve the accessibility of new derivatives of thia diazolopyrimidinones from a common starting material without the need of tedious syntheses of the starting materials. Based on the pharmacological activity know (see above) and based on initial docking studies we expected that arylated thia diazolopyrimidinones might be promising nucleotide pyrophosphatase (NPPs) inhibitors. The carbonyl group and nitrogen atoms in the heterocyclic core structure are ideally located to interact with the enzyme. An additional important point was the accessibility of both a fluorinated and non-fluorinated series based on our synthetic experience with this type of molecule. Fluorine present in heterocyclic core structures can have an important impact on the biological activity, because of the metabolic stability of the C–F bond and because of a change of the electronic situation combined with increased lipophilicity. Therefore, the thia diazolopyrimidone core structure allowed us to investigate fluorinated and non-fluorinated core structures, besides the presence of fluorine in selected aryboronic acids used by us as mentioned above (Fig. 1).

Thia diazolopyrimidinones are easily available by simple condensation reactions of commercially available 2-aminothia diazole with corresponding β-ketoesters in an acidic reaction medium.\textsuperscript{26} Thus, functionalisation of positions 5 and 6 of thia diazolopyrimidinones is easily achieved by the choice of the appropriate β-ketoester. However, a functionalisation of position 2 is more complicated and requires corresponding aminothiadiazoles which have to be tediously synthesized (Fig. 2).\textsuperscript{27}

Recently, the groups of Shukurov and Kukaniev synthesized 2-bromothia diazolopyrimidinones by simple bromination of aminothia diazole and subsequent condensation with several β-ketoesters.\textsuperscript{28} Products were applied in SNAr reactions using N- and S-nucleophiles as well as CH-acidic carbonyl compounds. We decided to investigate the functionalisation of 2-bromothia diazolopyrimidinones by the Suzuki–Miyaura cross-coupling protocol. This building-block strategy will give access to a broad variety of 2-arylated thia diazolopyrimidinones. For our study we chose 7-methyl-2-bromo-5H-[1,3,4]-thia diazolo[3,2-a]pyrimidin-5-one (a) as well as 2-bromo-6-fluoro-7-methyl-[1,3,4]-thia diazolo[3,2-a]pyrimidin-5-one (b), because of the importance of fluorine in biological active compounds, as model substrates (Fig. 3). A great variety of aryl substituents were successfully introduced. We have selected the aryl substituents based on their electronic and steric aspects and 17 sterically and electronically different groups were used. In addition, we varied the position of the substituents at the phenyl group. A variety of alkyl, aryl and oxygen containing substituents were used. In addition, electron withdrawing substituents, such as nitro and cyano, were successfully employed. Due to the considerable pharmacological importance of fluorinated aryl groups, we also used three different fluorinated substituents. We then investigated these derivatives as potential inhibitors of nucleotide pyrophosphatase/phosphodiesterase-1 (h-NPP1) and h-NPP3. The effects of these molecules were also tested on four other human ectonucleotidases, nucleoside triphosphate diphosphohydrolases (NTPDase) i.e. h-NTPDase1, h-NTPDase2, h-NTPDase3 and h-NTPDase8.

Results and discussion

At first we synthesised 2-bromo-thia diazole 2 by simple bromination using commercially available 2-aminothia diazole 1 and elemental bromine in acetic acid. Afterwards, 2-bromothia diazolopyrimidinones 4a and 4b were synthesized by condensation of 2 with appropriate β-ketoester 3a and 3b (Scheme 1).

With brominated thia diazolopyrimidinones 4a and 4b in hand, we started to test the arylation by the Suzuki–Miyaura reaction. As a first trial we used compound 4a as the starting material and adapted conditions from Copin et al., who synthesised arylated imidazothiadiazoles using Pd(OAc)\textsubscript{2} in the presence of bidentate xantphos ligand, but using conventional heating instead of a microwave reactor.\textsuperscript{29} Moreover, we used o-tolylboronic acid as a nucleophile. Using these conditions, we isolated the desired product 5a in excellent 88% yield. Thus, no further optimization of the reaction condition was required and
we started to test the scope of the reaction condition with 4a (Table 1).

All compounds were isolated in very good yields using ortho-, meta- or para-substituted arylboronic acids. Using para-chlorophenylboronic acid led to slightly diminished 65% yields, which might be a result of a cross-coupling reaction at the carbon–chlorine bond as a side-reaction.

Next we evaluated starting material 3b in this reaction. This fluorinated starting material worked well in the cross-coupling reaction and delivered corresponding products in very good yields ranging from 50–92% yield. Electron-rich and electron-poor arylboronic acids gave good isolated yields (Table 2). 4-Trifluoromethoxyphenylboronic acid 4p resulted in reduced yields what is due to problems during the purification process by column chromatography. However, comparing starting materials 3a and 3b, 3b gave slightly improved yields of cross-coupling products which might be explained by the electron-withdrawing nature of the fluorine substituent and according activation of the aryl halide.

Structure–activity relationship
Suramin is a well-known polyanionic compound that binds to almost all ecto-nucleotidases, but inhibited both NTPDases and NPPs non-selectively. It inhibited h-NTPDase1, 2, 3 & 8 with inhibitory value of 16.1 ± 1.02, 24.1 ± 3.01, 4.31 ± 0.41 & >100 μM, respectively, while it inhibited h-NPP1 & 3 with inhibitory value of 8.67 ± 1.3 and 1.27 ± 0.08 μM, respectively. Our newly synthesized derivatives of 2-bromo-7-methyl-5H-[1,3,4]thiadiazolo[3,2-a]pyrimidin-5-one (4a) i.e. 5a–5i, and 2-bromo-6-fluoro-7-methyl-5H-[1,3,4]thiadiazolo[3,2-a]pyrimidin-5-one (4b) i.e. 6a–6q were evaluated for their inhibitory potential on h-NTPDases and h-NPPs. It was found that these compounds, in comparison to NTPDases, were identified as selective inhibitors of NPPs even at lower concentrations i.e. 100 μM. These compounds exhibited low inhibitory response i.e. below 50% on four isozymes of h-NTPDase. Except 5a, all the derivatives of either 4a or 4b exhibited dual inhibition of both isozymes of NPPs but exhibited more selective inhibition of h-NPP1.

The detailed structure–activity relationship of aryalted products derived from 2-bromo-7-methyl-5H-[1,3,4]thiadiazolo[3,2-a]pyrimidin-5-one (4a) suggested that the introduction of 4-chlorophenyl substrate at position 2 of 4a led to a potent inhibitor 5i. This compound (5i) was found to be the most potent inhibitor of h-NPP1 (IC_{50} ± SEM = 0.39 ± 0.01 μM) exhibiting ≈23 fold more inhibition than the reference control used i.e. Suramin (IC_{50} ± SEM = 8.67 ± 1.3 μM). It can be suggested that the more inhibitory potential of this compound might be due to the presence of less reactive substituent, i.e. 4-chlorophenyl at position 2 of 4a which make the ring stable. This was further justified by comparing the activity of this compound with the other derivatives having more reactive substituent. For example, introduction of methyl group at o, m- or p-position (5g, 5h & 5a) resulted in reduced activity, in comparison to 5i. In this case, dimethyl substitution (5g & 5h) showed better improvement in inhibitory potential as compared to the mono-substituted methyl (5a). Interestingly, dimethyl substitution at m-position exhibited high inhibitory potential i.e. IC_{50} ± SEM = 0.41 ± 0.01 μM, however, the activity was only moderately reduced when one m-methyl group was shifted to p-position of phenyl ring (5h) i.e. IC_{50} ± SEM = 0.43 ± 0.02 μM. This shifting of methyl group from m- to p-position was appeared to be essential for h-NPP3 activity. Likewise, the replacement of the disubstituted methyl group by mono-substituted methyl group from m- to p-position (5a) reduced or nearly abolished the activity against h-NPP1 but exhibited improved inhibitory potential against h-NPP3 with IC_{50} value of 2.19 ± 0.22 μM. Interestingly, the potency against h-NPP1 was greatly reduced when the 4-chlorophenyl was replaced by 4-ethoxyphenyl as in 5e or 4-methoxyphenyl as in 5d or ethylated phenyl as in 5e (Table 2). The reason behind this effect might be due to the presence of ethoxy and methoxy groups which are electron donating, less reactive than methyl and are moderately activating the benzene ring. As a result of this, it increases electronic cloud, produces more steric hindrance, less reactivity of the compound and ultimately exhibited less inhibitory potential.

The set of fluorinated 5H-[1,3,4]thiadiazolo[3,2-a]pyrimidin-5-ones derived from 4b, i.e. 6a–6q exhibited more significant inhibitory results as compared to products derived from non-fluorinated educt 4a. The obtained results suggested that the presence of fluorine at 6-position of the ring is responsible for the improvement in inhibitory values. As presence of electronegative fluorine increases the electron density on thiadiazolopyrimidine ring, thus the substitution of less reactive group at phenyl ring attached at position 2 resulted in the improvement of inhibitory values towards both isozymes. An interesting behavior was observed in case of 4-chlorophenyl substitution i.e. derivative 6l. It exhibited less inhibition of h-NPP1 as compared to 5i due to the presence of two electronegative atoms i.e. F and Cl which decreases the electron density on the functional ring i.e. thiadiazolopyrimidine and make the ring unstable. It was observed that introduction of more reactive methyl as 3,5-dimethylphenyl at position 2 of 4b, led to the potent inhibitor 6e. This compound was found to be the most
potent inhibitor of h-NPP1 with the inhibitory value of 0.31 ± 0.01 μM, exhibiting maximum inhibition of h-NPP1 and it was found that this compound exhibited ~28 fold improvement in inhibitory potential than the used reference control i.e. Suramin (IC_{50} ± SEM = 8.67 ± 1.3 μM). The shifting of one methyl group from m-position to p-position (6d) or introduction of single methyl group in the p-position (6a) led to a decrease in the activity of >4-fold as compared to 6e. The introduction of m-substituted phenyl ring with electron withdrawing nitrogroup i.e. 3-nitrophenyl (6f), dramatically decreased the inhibitory activity against both h-NPPs. The effect was observed because of presence of nitro group at m-position of the ring, where it strongly deactivated the phenyl ring.

Likewise, the introduction of m- or p-substituted phenyl ring with electron donating methoxy group exhibited interesting behavior. For example: p-substituted phenyl ring, i.e. in case of 3-methoxy phenyl 6i, led to 4 fold improved inhibition of h-NPP1 as compared to h-NPP3. Reverse effect was observed when phenyl ring was di-substituted at m-position, i.e. 3,5-dimethoxyphenyl in case of 6j resulted in reduced inhibition of h-NPP1 but 2 fold improved inhibitory value against h-NPP3. The introduction of a halogen (chlorine or fluorine) substituent in the p- and m-position (6l & 6m) exhibited almost equipotent inhibitory activity against both h-NPPs i.e. h-NPP31 & 3.

It can be concluded from the obtained results that in case of 4a derivatives, substitution of electron withdrawing group i.e. Cl resulted in improved inhibitory potential towards h-NPP1. While in case of 4b derivatives, substitution with electron-negative atom resulted in decreased inhibition of h-NPP1. Moreover, disubstitution of phenyl ring with electron donating groups at m-position, in both 4a and 4b derivatives, justifying the improved inhibition toward both isozymes (Table 3).

**Mechanism of inhibition.** Detailed kinetics studies were carried out for compound 6e and 6j, the most potent inhibitor of h-NPP1 and h-NPP3, respectively. The Lineweaver–Burk plot of both compounds visualizes the competitive mechanism of inhibition by showing the same y-intercept for uninhibited and inhibited enzyme (Fig. 4 and 5).

**Homology modelling of human NPP1 and NPP3**

Homology modelling is the most reliable and extensively used method for prediction of 3D structure of a protein in the absence of X-ray/NMR structures of target proteins.30 X-ray crystallographic structures of h-NPP1 and h-NPP3 are not available in protein data bank. For this purpose homology modelling approach was used to predict the 3D model of targets, h-NPP1 and h-NPP3 enzymes. X-ray crystallographic
structure of mouse ectonucleotide pyrophosphatase-phosphodiesterase-1 (m-ENPP1, PDB ID 4B56) was used as template model to generate the homology model of target proteins. Homology modelling of target proteins were performed as that of previously reported method, via Molecular Operating Environment (MOE 2104.0901). Modelled structures of both targets i.e. h-NPP1 and h-NPP3 exhibited 80% and 52% sequence identity with template m-NPP1, respectively. Sequence and structural alignment of modelled proteins with template protein were also performed using superimpose and align utilities of MOE 2104.0901 (depicted in ESI†). Energy minimization, protonation and tautomer state of the amino acids were fixed using in-built utilities of MOE package such as Amber12:EHT and Protonate 3D. RMSD between h-NPP1 modelled protein and m-NPP1 template protein was 0.613 Å over 816 residues while RMSD between h-NPP3 modelled protein and m-NPP1 template protein was 1.349 Å over 811 residues. interaction with each other inside the active sites of modelled structure of target enzymes. Both potent compounds formed two hydrogen bonds (green dotted line) and two pi–cation interaction (gold dotted line) inside the active site of both modelled target, h-NPP1 and h-NPP3. Carbonyl oxygen of pyrimidine ring in both compounds formed one hydrogen bond with Asn277 in h-NPP1 and h-NP3 with a distance of 2.74 Å and 2.93 Å respectively. Substituted fluorine in pyrimidine ring in both potent compounds 6e and 6j also formed one hydrogen bond with Leu290 with a distance of 2.53 Å and 2.03 Å respectively. Pyrimidine and thiadiazole ring in both potent compounds also formed two pi–cation interactions with amino acid Lys278 with a distance of 4.01 Å and 3.95 Å inside the active site of both target enzymes. Each methoxy side chain in 6j compounds formed two additional hydrogen bonds in the active site of h-NPP3. In these two additional hydrogen bonds, one H-bond was formed between oxygen of one methoxy group and amino acid residue Lys255 with a distance of 1.99 Å while other H-bond was formed between oxygen of other methoxy group in compound 6j and amino acid residue Tyr451 with a distance of 2.03 Å inside the active site of h-NPP3.

Conclusions

In conclusion, we developed a new building block strategy for the synthesis of 2-arylated thiadiazolopyrimidones using the Suzuki–Miyaura reaction. Our reaction conditions allows the facile synthesis of the products in generally good to very good yields what is represented by the application of two different thiadiazolopyrimidones. All the compounds were selective inhibitors of NPPs with little effect on h-NTPDase1, h-NTPDase2, h-NTPDase3 and h-NTPDase8. In addition, our data suggested that most of the compounds presented here inhibited h-NPP1 more efficiently than h-NPP3. Therefore these compounds appear as more selective inhibitors of h-NPP1. The results reported herein are of considerable interest for further applications in medicinal chemistry.

Experimental section

General procedure for the synthesis of 2-substituted-7-methyl-5H-1,3,4-thiadiazolo[3,2-a]pyrimidin-5-one and 2-substituted-6-fluoro-7-methyl-5H-1,3,4-thiadiazolo[3,2-a]pyrimidin-5-one

Mixture of 2-bromo-7-methyl-5H-1,3,4-thiadiazolo[3,2-a]pyrimidin-5-one (1.0 equiv., 0.407 mmol) or 2-bromo-6-fluoro-7-methyl-1,3,4-thiadiazolo[3,2-a]pyrimidin-5-one (1.0 equiv., 0.379 mmol), arylboronic acid (1.1 equiv.), palladium(II)acetate (0.1 equiv.), xantphos (0.2 equiv.), potassium carbonate (2.0 equiv.) was vigorously stirred and heated in dry 1,4-dioxane (2 mL) at 100 °C for 16 h. After cooling to room temperature, the reaction was diluted with water and extracted into ethyl acetate. The organic layer was dried with anhydrous sodium sulfate and the solvent was evaporated. The crude compound was purified by flash column chromatography on silica gel (ethyl acetate : heptane).

7-Methyl-2-(2-methylphenyl)-5H-1,3,4-thiadiazolo[3,2-a]pyrimidin-5-one (5a). According to the general procedure, using 2-methylphenylboronic acid afforded 100 mg of product 5a (88%) as a yellow solid; mp (135–136 °C); 1H NMR (250 MHz, CDCl3) δ 7.60–7.63 (m, 1H, CHAr), 7.41–7.47 (m, 1H, CHAr), 7.28–7.36 (m, 2H, CHAr), 6.32 (d, J = 0.60 Hz, 1H, CHHet-Ar), 2.64 (s, 3H, CH3), 2.38 (br, s, 3H, CH3); 13C NMR (62 MHz, CDCl3) δ 163.40 (CAr), 161.34 (CAr), 158.78 (CAr), 157.09 (CAr), 137.99 (CAr), 132.07 (CAr), 131.94 (CHAr), 130.48 (CHAr), 127.54 (CHAr), 126.63 (CHAr), 107.73 (CHhet-Ar), 23.96 (CH3), 21.56 (CH3); IR (ATR) ν 3054 (w), 2962 (w), 2921 (w), 1681 (s), 1576 (s), 1498 (s), 1440 (m), 1390 (m), 1364 (m), 1249 (m), 1033 (w), 964 (m), 825 (m), 766 (s), 696 (m), 609 (cm⁻¹); MS m/z 257 [M⁺, 100], **RSC ADVANCES**
According to the general procedure, using 3-methylphenylboronic acid afforded 85 mg of product 5b (73%); yellow solid; mp (167–168 °C); 1H NMR (300 MHz, CDCl3) δ 7.83 (d, J = 0.54 Hz, 1H, CHAr), 7.34 (d, J = 8.82 Hz, 2H, CHAr), 6.32 (d, J = 0.75 Hz, 1H, CH_{\text{Het-Ar}}), 2.73 (q, J = 7.55 Hz, 2H, CH2), 2.39 (d, J = 0.75 Hz, 3H, CH3); 13C NMR (62 MHz, CDCl3) δ 163.16 (CAr), 161.09 (CAr), 158.93 (CAr), 154.15 (CAr), 134.18 (CAr), 129.16 (CAr), 128.05 (CH2Ar), 125.95 (CHAr), 107.95 (CH_{\text{Het-Ar}}), 28.95 (CH2), 23.94 (CH3), 15.32 (CH3); IR (ATR) ν 3485 (w), 3049 (w), 2954 (w), 2878 (w), 1702 (s), 1574 (s), 1496 (s), 1305 (s), 1259 (s), 1172 (m), 1029 (m), 824 (m), 699 (m), 603 (m) cm⁻¹; MS m/z 257 (M⁺, 100), 245 (8), 151 (41), 133 (23), 112 (81), 94 (16); HRMS calcd for C_{13}H_{11}O_{2}N_{3}S: C, 57.13; H, 4.06; N, 15.37; S, 11.73 found: C, 57.51; H, 4.44; N, 15.74; S, 12.08.

According to the general procedure, using 4-ethoxyphenylboronic acid afforded 79 mg of product 5e (70%); brown solid; mp (151–152 °C); 1H NMR (300 MHz, CDCl3) δ 7.88 (d, J = 8.98 Hz, 2H, CHAr), 6.98 (d, J = 8.98 Hz, 2H, CHAr), 6.31 (d, J = 0.78 Hz, 1H, CH_{\text{Het-Ar}}), 4.11 (q, J = 7.00 Hz, 2H, OCH2), 2.37 (d, J = 0.63 Hz, 3H, CH3), 1.45 (t, J = 6.93 Hz, 3H, CH3); 13C NMR (62 MHz, CDCl3) δ 163.16 (CAr), 160.99 (CAr), 158.68 (CAr), 157.20 (CAr), 129.66 (CAr), 126.65 (CHAr), 115.34 (CHAr), 64.13 (OCH2), 23.90 (CH3), 14.77 (CH3); IR (ATR) ν 3050 (w), 2982 (w), 2936 (w), 2873 (w), 1702 (s), 1693 (s), 1605 (s), 1496 (s), 1384 (m), 1316 (w), 1259 (s), 1172 (m), 1029 (m), 824 (m), 699 (m), 603 (m) cm⁻¹; MS m/z 287 (M⁺, 100), 259 (7), 159 (11), 137 (19), 112 (62), 94 (8); HRMS calcd for C_{14}H_{13}O_{2}N_{3}S: C, 58.52; H, 4.56; N, 14.64; S, 11.16 found: C, 58.51; H, 4.49; N, 15.04; S, 11.08.

According to the general procedure, using 3,5-dimethoxyphenylboronic acid afforded 100 mg of product 5f (81%); brown solid; mp (219–220 °C); 1H NMR (300 MHz, CDCl3) δ 7.84 (d, J = 7.83 Hz, 2H, CHAr), 6.62 (t, J = 2.23 Hz, 1H, CH_{\text{Het-Ar}}), 6.32 (d, J = 0.69 Hz, 1H, CH_{\text{Het-Ar}}), 3.85 (s, 6H, OCH3), 2.38 (d, J = 0.60 Hz, 3H, CH3); 13C NMR (62 MHz, CDCl3) δ 163.51 (CAr), 161.47 (CAr), 161.02 (CAr), 158.93 (CAr), 157.21 (CAr), 143.53 (CAr), 130.06 (CH_{\text{Het-Ar}}), 107.85 (CH_{\text{Het-Ar}}), 105.77 (CHAr), 55.95 (OMe), 23.98 (CH3); IR (ATR) ν 3486 (m), 3449 (m), 3052 (w), 2953 (w), 1668 (s), 1564 (s), 1501 (s), 1362
7-Methyl-2-(3,5-dimethylphenyl)-5H-1,3,4-thiadiazolo[3,2-a]pyrimidin-5-one (5g). According to the general procedure, using 3,5-dimethylphosphonic acid afforded 88 mg of product 5g (79%); yellow solid; mp (216–217 °C); 1H NMR (250 MHz, CDCl3) δ 7.55 (s, 2H, CH₂Ar), 7.19 (s, 1H, CHAr), 6.31 (s, 1H, CH₃), 2.37 (s, 9H, CH₃); 13C NMR (62 MHz, CDCl₃) δ 163.36 (CAr), 161.10 (CAr), 159.30 (CAr), 157.22 (CAr), 139.42 (CAr), 134.83 (CAr), 128.19 (CAr), 125.55 (CH₂Ar), 107.29 (CH₃), 23.96 (CH₃), 21.19 (CH₃); IR (ATR) ν 3038 (w), 2964 (w), 2914 (w), 1690 (s), 1567 (s), 1492 (s), 1354 (w), 1198 (w), 854 (m), 867 (m) cm⁻¹; MS m/z 271 (M⁺, 100), 243 (12), 149 (22), 131 (11), 112 (82), 103 (7); HRMS calcd for C₁₄H₁₃ON₃S 271.07738 found 271.07750; anal. calcd for C₁₄H₁₃ON₃S: C, 56.01; H, 4.49; N, 13.34; S, 11.08.

According to the general procedure, using 3,4-dimethylphosphonic acid afforded 85 mg of product 5h (77%); yellow solid; mp (175–176 °C); 1H NMR (300 MHz, CDCl₃) δ 7.75 (d, 3J = 1.38 Hz, 1H, CHAr), 7.60 (dd, 3J = 7.83 Hz, 1J = 1.76 Hz, 1H, CH₂Ar), 7.23 (d, 1J = 7.83 Hz, 1H, CHAr), 6.30 (s, 1H, CH₃), 2.36 (s, 9H, CH₃); 13C NMR (62 MHz, CDCl₃) δ 163.31 (CAr), 161.10 (CAr), 159.17 (CAr), 157.24 (CAr), 142.75 (CAr), 138.21 (CAr), 130.62 (CAr), 128.54 (CH₂Ar), 125.92 (CH₂Ar), 125.47 (CH₃Ar), 107.76 (CH₃Ar), 23.96 (CH₃), 20.13 (CH₃), 19.68 (CH₃); IR (ATR) ν 3563 (m), 3454 (m), 3043 (w), 2945 (w), 1685 (s), 1567 (s), 1488 (s), 1394 (m), 1263 (m), 1124 (m), 977 (m), 861 (m), 741 (m), 695 (m), 623 (m) cm⁻¹; MS m/z 271 (M⁺, 100), 243 (10), 149 (17), 133 (13), 112 (76), 85 (11); HRMS calcd for C₁₄H₁₂ON₃S 271.07738 found 271.07744; anal. calcd for C₁₄H₁₂ON₃S: C, 55.43; H, 4.32; N, 13.85; S, 10.57 found: C, 56.01; H, 4.49; N, 13.34; S, 11.08.

6-Fluoro-7-methyl-2-phenyl-5H-1,3,4-thiadiazolo[3,2-a]pyrimidin-5-one (6a). According to the general procedure, using phenylphosphonic acid afforded 91 mg of product 6a (92%); white solid; mp (206–207 °C); 1H NMR (300 MHz, DMSO) δ 8.00 (d, 3J = 6.75 Hz, 2H, CH₂Ar), 7.64–7.71 (m, 3H, CH₂Ar), 2.36 (d, 1J = 2.64 Hz, 3H, CH₃); 13C NMR (75 MHz, DMSO) δ 160.16 (CHₓ), 155.80 (d, 3J = 3.35 Hz, CNNs), 150.36 (d, 3J = 27.50 Hz, CO), 146.37 (d, 1J = 16.85 Hz, C-CHₓ), 144.41 (d, 1J = 241.41 Hz, C-FHₓ), 133.17 (CHAr), 129.76 (CH₂Ar), 128.12 (CH₂Ar), 127.47 (CH₂Ar), 17.11 (CH₂Ar); IR (ATR) ν 3016 (w), 2967 (w), 2923 (w), 1720 (w), 1684 (s), 1585 (s), 1506 (s), 1482 (m), 1445 (m), 1362 (s), 1203 (s), 983 (m), 880 (m), 772 (s), 685 (s) cm⁻¹; MS m/z 261 (100), 130 (10), 105 (9), 90 (10); HRMS calcd for C₁₂H₁₀NO₃S 261.03665; anal. calcd for C₁₂H₁₀NO₃S: C, 55.16; H, 3.09; N, 16.08; S, 12.27. 6-Fluoro-7-methyl-2-(3-cyanophenyl)-5H-1,3,4-thiadiazolo[3,2-a]pyrimidin-5-one (6q). According to the general procedure, using 3-cyanophenylboronic acid afforded 83 mg of product 6q (77%); white solid; mp (210–211 °C); 1H NMR (300 MHz, CHCl3)
δ 8.19–8.25 (m, 2H, CHAr), 7.88–7.91 (m, 1H, CHAr), 7.68–7.73 (m, 1H, CHAr), 2.44 (d, J = 3.78 Hz, 3H, CH3); 13C NMR (62 MHz, CDCl3) δ 156.37 (d, J = 247.79 Hz, C-Fhet-Ar), 150.85 (CAr), 147.62 (d, J = 17.11 Hz, C-CH3), 143.12 (CAr), 140.04 (d, J = 28.37 Hz, CO), 136.11 (CAr), 131.59 (CAr), 131.08 (CHAr), 130.63 (CHAr), 129.73 (CHAr), 117.15 (CHAr), 114.38 (CN), 17.60 (CH3); IR (ATR) ν 3054 (w), 3031 (w), 2917 (w), 1694 (s), 1592 (s), 1483 (m), 1288 (m), 1155 (w), 848 (m), 805 (m), 761 (s), 744 (s), 684 (s), 628 (m) cm⁻¹; MS m/z 286(100), 228(12), 146(23), 130(43), 128(46), 102(17); HRMS calcd for C13H7ON4FS: C, 54.54; H, 2.46; N, 19.57; S, 11.20.

Nucleotide pyrophosphatase inhibition assay

The inhibitory effect of all the derivatives on nucleotide pyrophosphatase (h-NPP1 & h-NPP3) was carried out according to our previously reported method.44 The reaction buffer used for this assay was consisted of 5 mM MgCl₂, 0.1 mM ZnCl₂, 50 mM Tris–HCl (pH 9.5) and 25% glycerol. To the total assay volume of 100 μL, 10 μL of tested compound solution was added (at 0.1 mM final concentration) followed by the addition of 10 μL of h-NPP1 (final conc. of 27 ng) or h-NPP3 (final conc. of 25 ng). The reaction mixture was allowed to incubate for 10 min at 37 °C and absorbance was measured at 405 nm using microplate reader (BioTek ELx800, Instruments, Inc. USA). Then 10 μL of substrate p-nitrophenyl-5′-thymidine monophosphate (p-Nph-5′-TMP, 0.5 mM) was added to initiate the reaction and the mixture was allowed to incubate at 37 °C. The change in absorbance was measured after 30 min. The compounds which exhibited over 50% inhibition of enzyme activity were further selected for evaluation of IC₅₀ values. All experiments were carried out in triplicate. The IC₅₀ values were calculated by using non-linear regression analysis of program PRISM 5.0 (GraphPad, San Diego, California, USA).

Mechanism of inhibition. To further characterize the interaction of most potent inhibitors of h-NPP1 and h-NPP3, the type of inhibition was determined by Michaelis–Menten kinetics. For this purpose, the initial rates of the enzyme inhibition at four different substrate concentrations (125 μM, 250 μM, 500 μM and 750 μM) in the absence and in the presence of four different concentrations (0 μM, 0.50 μM, 1.00 μM and 2.00 μM) of the selected representative inhibitor 6e against h-NPP1 and 6j against h-NPP3 were measured. The results are illustrated as double reciprocal Lineweaver–Burk plots in Fig. 4 and 5.

Homology modelling of human NPP1 and NPP3

Homology modelling of target proteins that is h-NPP1 and h-NPP3 was carried out using MOE (2014.0901) package. Amino acid sequence of h-NPP1 and h-NPP3 were downloaded from NCBI protein database. UniprotKB/Swiss-prot ID P22413 of h-NPP1 and accession code O14638 for human NPP3 were retrieved from NCBI protein data bank and loaded to MOE. Identification of suitable template protein structures were investigated by BLOSUM62 and then incorporated in MOE package.43 X-rays crystallographic structure of mouse Enpp1 (PDB ID 4B56) from rcsb protein data bank was used as a template structure for homology modelling of our target proteins. Total ten homology models of target protein were generated. Among these ten model structures one best model
was selected and refined using Amber12:EHT\textsuperscript{45,46} force field. The protonation of the model proteins was also carried out using built-in Protonate-3D tool in MOE. Validation and comparison of homology models with the X-ray template structure was performed by re-aligning and superimposing with each other. Align sequence and structural alignment utilities of MOE were used for aligning and sequencing the modelled proteins with template protein. The RMSD values for modelled proteins were found out and Ramachandran plots were generated for both modelled proteins (see ES\textsuperscript{I}).

**Molecular docking studies.** Molecular docking of the most active inhibitor 6e and 6j of h-NPP1 and h-NPP3 respectively, were performed to find out the putative binding mode in the active site of modelled enzymes. Firstly, the chemical structures of the most potent compounds were generated using builder tool and then 3D optimized in Molecular Operating Environment (MOE) 2014, 09 software.\textsuperscript{39} Prior to molecular docking studies protonation and energy minimization of all modelled structures of both targets were performed using MOE. After prerequisite preparation of inhibitors as well as target enzymes AutoDock4 and AutoDock Tool were used to perform molecular docking studies.

Grid box having dimension of $60 \times 60 \times 60$ in XYZ direction was built over both targets and centroid on the active site of target enzymes. Lamarckian genetic algorithm (LGA) was used was built over both targets and centroid on the active site of template protein. The RMSD values for modelled proteins were found out and Ramachandran plots were generated for both modelled proteins (see ES\textsuperscript{I}).
