Regulation of the quality of the environment must ensure environmental safety of the population and the preservation of the gene pool, to ensure rational use and reproduction of natural resources in the context of sustainable development of economic activities.

Environmental regulation is one of the most effective means of environmental protection and rational use of natural resources [1]. The permissible load on the ecosystem is regulated and the boundaries of the impact of economic activity on the environment are established with it.

As a general and informative indicator of air pollution is a comprehensive pollution index (CPI)-complex index of annual average atmospheric pollution. Its quantitative ranking by the class of state of the atmosphere is shown in table 1.

Table 1

Indicators	Classes of ecological status of the atmosphere			
	Rates(N)	risk (R)	crisis (K)	Disasters (D)
Levels of air pollution	<5	5-8	8-15	>15

Air pollution in the city of Almaty is an acute environmental problem, which is complicated by the geographic and climatic conditions. For the study of air pollution in the city estimates of the content of harmful substances in the atmosphere of the city were analyzed. Accounts for air pollution in the city Almaty are lead with 5 types of pollutants.

By the program “Era-Air” the maximum one-time emissions and surface concentration for enterprise TPP-2 of Almaty that burn high-ash Ekibastuz coal were calculated. The installed power capacity of TPP-2 -510 megavolt, thermal capacity - 1176 Gcal/h.

Basic characteristics of Ekibastuz coal, which is burnt at TPP-2, are shown in Table 2.

Software package of “Era-Air” is devoted to a wide range of problems in the field of air associated with the calculations of air pollution.

Using the program in the work single emission ash, oxides of sulfur, carbon, nitrogen, which formed from the combustion of Ekibastuz coal, characteristics, which are listed above, with the height of the chimney 120 meters were calculated. The calculation results are shown in Table 3.

According to our calculations, during the burning of high-ash coal, the maximum amount of one-off emissions from a point source exceed at 10 times the maximum single concentration, therefore, the average daily concentration will also be significantly higher than the maximum permissible concentration.

As can be seen from the calculation, the maximum surface concentration of greenhouse gases exceeds the average daily concentration.

It was found that the burning of Ekibastuz coal emits large amounts of pollutants, the concentration of which exceeds the maximum single and daily average concentration of impurities, on average, 2 times the permissible limit values of maximum permissible concentration. This leads to an increase in complex index of air pollution of the city of Almaty, which is higher than officially known air pollution index is 12. CPI normally should not exceed 5. The calculated figure shows the complex exceeded air pollution of the city of Almaty in 2 times

In this regard, our work provides a new way to reduce greenhouse gas emissions on the atmosphere. Different ways of disposing of greenhouse gases contained in industrial emissions widely used in practice. However, it may be appropriate to reduce emissions by improving the quality of fuel burned, increase the efficiency of its combustion. To modify the Ekibastuz coal quality in our work, we conducted research on the effect of electron beam processing on the physical and chemical properties of coal, increasing the efficiency of its combustion in order to reduce emissions

We studied the impact of the accelerated electron beam on the structure of coal. Experiments on radiation processing of coal were carried out on an electron accelerator ILU-8. Accelerator generate electrons with an energy of 1.3 MeV, power of dose vary from 0.19 to 0.33 Mrad/s, the total dose of absorption - from 10 to 200 Mrad/s, the total dose of uptake - from 10 to 200Mrad. The temperature of the coal layer thickness of 7 mm was monitored using a thermocouple and maintained in the range 60-70 and 250-260°C.

Preliminary electron beam processing of coal results in lower emissions reduces the amount of ash and reduces the maximum one-time emissions (table 2-3) at least from 0.6% to 9% for the different greenhouse gases.

Table 2

Fuel	humidity $W_p$ %	volatility, $V_{daf}$ %	ifur, $S_d$ %	ash content, $A_d$ %	carbohydra tes., $C_{daf}$ %	hydrogen $H_{daf}$ %	nitrogen, $N_{daf}$ %	oxygen, $O_{daf}$ %	combustion heat, $Q_p$ MJ / kg
no exposure	8.43	28	0.7	43	43.3	2.64	0.79	6.07	16.83
Radiation	6.41	26	0.5	39	45	3.1	0.7	7.2	16.5

Results of calculation of the maximum single-emission (by the program “Era”) are shown in Table 3.

Table 3

Fuel	Maximum one-time emissions, g/s			
	Ash	sulfur dioxide SO <sub>2</sub>	nitrogen oxides NO	carbon monoxide M <sub>CO</sub>
no exposure	57.91	12.6	3	16
radiation	52.6	9	3.08	15

In view of the above, results, which obtained in this study may help to solve the problems associated with the implementation of Kazakhstan's commitment to reduce air pollution, the development of green economy.

Conducting pilot tests of the electron beam by a point is necessary for the widespread introduction of the proposed method directed to modification of fuel, improving the quality of the environment. Industrial electron accelerator ILU-8 capacity of 95 kilowatts works in the industrial park of Almaty, which has high performance and can be used technologically complex by electron beam processing of different materials.

Выделим элементарный напряженно-деформированный объем смазочного материала. Будем считать, что он погружен в термостат - невозмущенная часть смазочного материала. Квантовые переходы, связанные с полем деформаций, приводят к диссипации энергии внешнего поля. Если считать, что выделенный объем обменивается с термостатом только энергией, то соответствующий ансамбль частиц выделенного элементарного объема будет каноническим. Функция отклика такого ансамбля на внешнее воздействие получена в работе [1]. Если в качестве функции отклика взять кинематическую вязкость  $\nu$ , то получим следующее выражение:

$$\nu = C \cdot \frac{A}{G^0}, \quad (1)$$

где  $G^0$  - энергия Гиббса термостата,  $A$  - работа внешних сил,  $C$  - постоянная.

Энергия внешних сил расходуется на разрыв молекулярных связей смазочного материала и равна  $A = \sigma \cdot S$  ( $\sigma$  - поверхностное натяжение,  $S$  - площадь поверхности элементарного объема). Тогда уравнение (1) примет вид:

$$\nu = C \cdot \frac{\sigma}{G^0}, \quad (2)$$

Уравнение (2) выражает связь между кинематической вязкостью и поверхностным натяжением жидкой среды (смазочного материала).

По мнению ряда исследователей вязкость и поверхностное натяжение – абсолютно независимые величины: вязкость – это динамическое явление (поперечные силы), а поверхно-
